### **Using Subqueries to Solve Queries**

### **Objectives**

After completing this lesson, you should be able to do the following:

- Define subqueries
- Describe the types of problems that the subqueries can solve
- List the types of subqueries
- Write single-row and multiple-row subqueries

### ORACLE!

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

In this lesson, you learn about the more advanced features of the SELECT statement. You can write subqueries in the WHERE clause of another SQL statement to obtain values based on an unknown conditional value. This lesson also covers single-row subqueries and multiple-row subqueries.

### Lesson Agenda

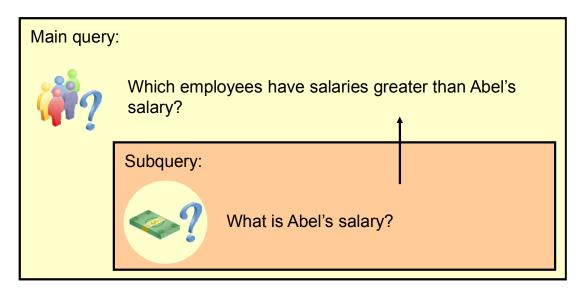

- Subquery: Types, syntax, and guidelines
- Single-row subqueries:
  - Group functions in a subquery
  - HAVING clause with subqueries
- Multiple-row subqueries
  - Use ALL or ANY operator.
- Using the EXISTS operator
- Null values in a subquery

**ORACLE** 

Oracle University and Egabi Solutions use only

### Using a Subquery to Solve a Problem

Who has a salary greater than Abel's?

ORACLE!

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

Suppose you want to write a query to find out who earns a salary greater than Abel's salary.

To solve this problem, you need two queries: one to find how much Abel earns, and a second query to find who earns more than that amount.

You can solve this problem by combining the two queries, placing one query *inside* the other query.

The inner query (or *subquery*) returns a value that is used by the outer query (or *main query*). The execution plan of the guery depends on the optimizer's decision on the structure of the subquery.

### **Subquery Syntax**

- The subquery (inner query) executes *before* the main query (outer query).
- The result of the subquery is used by the main query.

```
SELECT
         select list
FROM
         table
WHERE
         expr operator
                                     select list
                      (SELECT
                                     table);
                      FROM
```

ORACLE!

Oracle University and Egabi Solutions use only

A subquery is a SELECT statement that is embedded in the clause of another SELECT statement. You can build powerful statements out of simple ones by using subqueries. They can be very useful when you need to select rows from a table with a condition that depends on the data in the table itself.

You can place the subquery in a number of SQL clauses, including the following:

- WHERE clause
- HAVING clause
- FROM clause

### In the syntax:

operator includes a comparison condition such as >, =, or IN

**Note:** Comparison conditions fall into two classes: single-row operators (>, =, >=, <, <>, <=)and multiple-row operators (IN, ANY, ALL, EXISTS).

The subquery is often referred to as a nested SELECT, sub-SELECT, or inner SELECT statement. The subquery generally executes first, and its output is used to complete the query condition for the main (or outer) query.

### **Using a Subquery**

```
SELECT last name,
                    salary
FROM
       employees
WHERE
       salary >
                   11000 <
                 (SELECT salary
                 FROM
                         employees
                         last name =
                 WHERE
                                       'Abel');
```

	LAST_NAME	2 SALARY
1	King	24000
2	Kochhar	17000
3	De Haan	17000
4	Hartstein	13000
5	Higgins	12008

ORACLE!

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

In the slide, the inner query determines the salary of employee Abel. The outer query takes the result of the inner query and uses this result to display all the employees who earn more than employee Abel.

## Oracle University and Egabi Solutions use only

### **Rules for Using Subqueries**

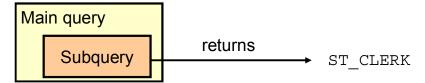

- Enclose subqueries in parentheses.
- Place subqueries on the right side of the comparison condition for readability. (However, the subquery can appear on either side of the comparison operator.)
- Use single-row operators with single-row subqueries and multiple-row operators with multiple-row subqueries.

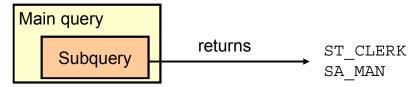

- A subquery must be enclosed in parentheses.
- Place the subquery on the right side of the comparison condition for readability. However, the subquery can appear on either side of the comparison operator.
- Two classes of comparison conditions are used in subqueries: single-row operators and multiple-row operators.

### **Types of Subqueries**

Single-row subquery

Multiple-row subquery

ORACLE!

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

- Single-row subqueries: Queries that return only one row from the inner SELECT statement
- Multiple-row subqueries: Queries that return more than one row from the inner SELECT statement

**Note:** There are also multiple-column subqueries, which are queries that return more than one column from the inner SELECT statement. These are covered in the Oracle Database: SQL Workshop II course.

### Lesson Agenda

- Subquery: Types, syntax, and guidelines
- Single-row subqueries:
  - Group functions in a subquery
  - HAVING clause with subqueries
- Multiple-row subqueries
  - Use ALL or ANY operator
- Using the EXISTS operator
- Null values in a subquery

ORACLE!

Oracle University and Egabi Solutions use only

### **Single-Row Subqueries**

- Return only one row
- Use single-row comparison operators

Operator	Meaning
=	Equal to
>	Greater than
>=	Greater than or equal to
<	Less than
<=	Less than or equal to
<>	Not equal to

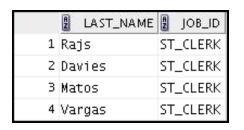

ORACLE

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

A single-row subquery is one that returns one row from the inner SELECT statement. This type of subquery uses a single-row operator. The slide gives a list of single-row operators.

### Example

Display the employees whose job ID is the same as that of employee 141:

### **Executing Single-Row Subqueries**

```
SELECT last name, job id,
                             salary
FROM
        employees
                                   SA REP
        job id =
WHERE
                  (SELECT job id
                           employees
                   FROM
                           last name =
                   WHERE
                                         'Taylor')
AND
        salary >
                  (SELECT
                           salary
                   FROM
                           employees
                           last name =
                   WHERE
                                         'Taylor')
    AST_NAME JOB_ID
                    SALARY
                     11000
            SA_REP
```

ORACLE!

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

A SELECT statement can be considered as a query block. The example in the slide displays employees who do the same job as "Taylor," but earn more salary than him.

The example consists of three guery blocks: the outer guery and two inner gueries. The inner query blocks are executed first, producing the query results SA REP and 8600, respectively. The outer query block is then processed and uses the values that were returned by the inner queries to complete its search conditions.

Both inner queries return single values (SA REP and 8600, respectively), so this SQL statement is called a single-row subquery.

**Note:** The outer and inner queries can get data from different tables.

### **Using Group Functions in a Subquery**

```
SELECT last name, job id,
                              salary
FROM
        employees
                                 2500
WHERE
        salary =
                    SELECT MIN(salary)
                    FROM
                            employees);
      LAST_NAME
              JOB_ID
                     SALARY
             ST_CLERK
```

ORACLE!

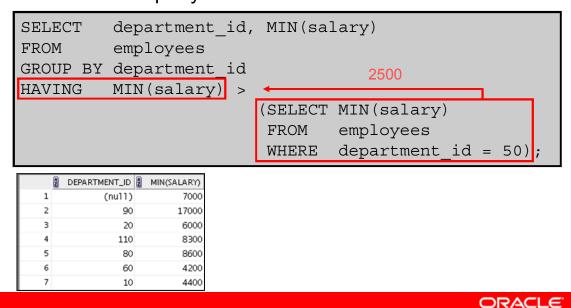

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

You can display data from a main query by using a group function in a subquery to return a single row. The subquery is in parentheses and is placed after the comparison condition. The example in the slide displays the employee last name, job ID, and salary of all employees whose salary is equal to the minimum salary. The MIN group function returns a single value (2500) to the outer query.

### **HAVING Clause with Subqueries**

- The Oracle server executes the subqueries first.
- The Oracle server returns results into the HAVING clause of the main query.

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

You can use subqueries not only in the WHERE clause, but also in the HAVING clause. The Oracle server executes the subquery and the results are returned into the HAVING clause of the main query.

The SQL statement in the slide displays all the departments that have a minimum salary greater than that of department 50.

### **Example**

Find the job with the lowest average salary.

1 ST\_CLERK

```
SELECT job_id, AVG(salary)

FROM employees

GROUP BY job_id

HAVING AVG(salary) = (SELECT MIN(AVG(salary))

FROM employees

GROUP BY job_id);
```

2925

### What Is Wrong with This Statement?

```
SELECT employee id, last name
FROM
       employees
WHERE
       salary =
                 (SELECT
                            MIN(salary)
                  FROM
                            employees
                  GROUP BY
                            department
                                        id)
```

ORA-01427: single-row subquery returns more than one row 01427, 00000 - "single-row subquery returns more than one row" \*Cause: \*Action:

Single-row operator with multiple-row subquery

ORACLE!

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

A common error with subqueries occurs when more than one row is returned for a single-row subquery.

In the SQL statement in the slide, the subquery contains a GROUP BY clause, which implies that the subquery will return multiple rows, one for each group that it finds. In this case, the results of the subquery are 4400, 6000, 2500, 4200, 7000, 17000, and 8300.

The outer query takes those results and uses them in its WHERE clause. The WHERE clause contains an equal (=) operator, a single-row comparison operator that expects only one value. The = operator cannot accept more than one value from the subquery and, therefore. generates the error.

To correct this error, change the = operator to IN.

### No Rows Returned by the Inner Query

```
SELECT last name, job id
FROM
       employees
WHERE
       job id =
                  (SELECT job id
                  FROM
                          employees
                  WHERE
                          last name =
                                       'Haas');
```

Subquery returns no rows because there is no employee named "Haas."

ORACLE!

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

Another common problem with subqueries occurs when no rows are returned by the inner query.

In the SQL statement in the slide, the subquery contains a WHERE clause. Presumably, the intention is to find the employee whose name is Haas. The statement is correct, but selects no rows when executed because there is no employee named Haas. Therefore, the subquery returns no rows.

The outer query takes the results of the subquery (null) and uses these results in its WHERE clause. The outer query finds no employee with a job ID equal to NULL, and so returns no rows. If a job existed with a value of null, the row is not returned because comparison of two null values yields a null; therefore, the WHERE condition is not true.

### Lesson Agenda

- Subquery: Types, syntax, and guidelines
- Single-row subqueries:
  - Group functions in a subquery
  - HAVING clause with subqueries
- Multiple-row subqueries
  - Use IN, ALL, or ANY
- Using the EXISTS operator
- Null values in a subquery

ORACLE!

Oracle University and Egabi Solutions use only

### **Multiple-Row Subqueries**

- Return more than one row
- Use multiple-row comparison operators

Operator	Meaning
IN	Equal to any member in the list
ANY	Must be preceded by =, !=, >, <, <=, >=. Returns  TRUE if at least one element exists in the result-set of the Subquery for which the relation is TRUE.
ALL	Must be preceded by =, !=, >, <, <=, >=. Returns  TRUE if the relation is TRUE for all elements in the result set of the Subquery.

**ORACLE** 

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

Subqueries that return more than one row are called multiple-row subqueries. You use a multiple-row operator, instead of a single-row operator, with a multiple-row subquery. The multiple-row operator expects one or more values:

### Example

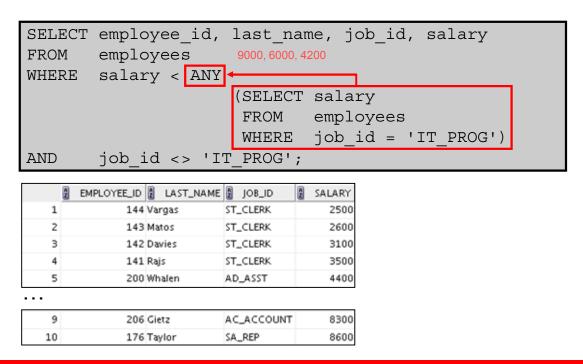

Find the employees who earn the same salary as the minimum salary for each department.

The inner query is executed first, producing a query result. The main query block is then processed and uses the values that were returned by the inner query to complete its search condition. In fact, the main query appears to the Oracle server as follows:

Oracle Database 12c: SQL Workshop I 8 - 17

# Oracle University and Egabi Solutions use only

### Using the ANY Operator in Multiple-Row Subqueries

**ORACLE** 

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

The ANY operator (and its synonym, the SOME operator) compares a value to *each* value returned by a subquery. The slide example displays employees who are not IT programmers and whose salary is less than that of any IT programmer. The maximum salary that a programmer earns is \$9,000.

- <ANY means less than the maximum.</li>
- >ANY means more than the minimum.
- =ANY is equivalent to IN.

### Using the ALL Operator in Multiple-Row Subqueries

```
last name, job id,
SELECT employee id,
                                           salary
FROM
       employees
                       9000, 6000, 4200
       salary < ALL
WHERE
                      (SELECT salary
                       FROM
                               employees
                       WHERE
                               job id = 'IT PROG'
AND
       job id <>
                  'IT
                       PROG';
```

	R	EMPLOYEE_ID	LAST_NAME	₿ JOB_ID	SALARY
1	Г	141	Rajs	ST_CLERK	3500
2		142	Davies	ST_CLERK	3100
3		143	Matos	ST_CLERK	2600
4		144	Vargas	ST_CLERK	2500

ORACLE!

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

The ALL operator compares a value to *every* value returned by a subquery. The example in the slide displays employees whose salary is less than the salary of all employees with a job ID of IT PROG and whose job is not IT PROG.

>ALL means more than the maximum and <ALL means less than the minimum.

The NOT operator can be used with IN, ANY, and ALL operators.

### Using the EXISTS Operator

```
SELECT employee id, salary, last name FROM employees M
WHERE EXISTS
(SELECT employee id FROM employees W
 WHERE (W.manager id=M.employee id) AND W.salary > 10000);
```

	A	EMPLOYEE_ID	A	SALARY	RN	LAST_NAME
1		100		24000	Κi	ng
2		149		10500	Z٦	otkey
3		101		17000	Κo	chhar

```
SELECT * FROM departments
WHERE NOT EXISTS
(SELECT * FROM employees
 WHERE employees.department id=departments.department id);
       DEPARTMENT_ID
                   DEPARTMENT_NAME
                                 MANAGER_ID
    1
               190 Contracting
                                               1700
```

ORACLE

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

The EXISTS operator is used in gueries where the guery result depends on whether or not certain rows exist in a table. It evaluates to TRUE if the subquery returns at least one row.

The first example in the slide displays managers in the EMPLOYEES table who earns a salary more than 10000. For each row in EMPLOYEES table, the condition is checked whether there exists a manager id who earns a salary more than 10000.

The second example in the slide displays departments that have no employees. For each row in the DEPARTMENTS table, the condition is checked whether there exists a row in the EMPLOYEES table that has the same department ID. In case no such row exists, the condition is satisfied for the row under consideration and it is selected. If there exists a corresponding row in the EMPLOYEES table, the row is not selected.

### Lesson Agenda Subquery: Types, syntax, and guidelines Single-row subqueries:

- Group functions in a subquery
- HAVING clause with subqueries
- Multiple-row subqueries
  - Use ALL or ANY operator
- Using the EXISTS operator
- Null values in a subquery

**ORACLE** 

Oracle University and Egabi Solutions use only

### **Null Values in a Subquery**

```
SELECT emp.last_name
FROM employees emp
WHERE emp.employee_id NOT IN

(SELECT mgr.manager_id
FROM employees mgr);
```

Subquery returns no rows because one of the values returned by a subquery is Null.

ORACLE!

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

The SQL statement in the slide attempts to display all the employees who do not have any subordinates. Logically, this SQL statement should have returned 12 rows. However, the SQL statement does not return any rows. One of the values returned by the inner query is a null value and, therefore, the entire query returns no rows.

The reason is that all conditions that compare a null value result in a null. So whenever null values are likely to be part of the results set of a subquery, do not use the NOT IN operator. The NOT IN operator is equivalent to <> ALL.

Notice that the null value as part of the results set of a subquery is not a problem if you use the IN operator. The IN operator is equivalent to =ANY. For example, to display the employees who have subordinates, use the following SQL statement:

Oracle University and Egabi Solutions use only

Alternatively, a WHERE clause can be included in the subquery to display all employees who do not have any subordinates:

### Quiz

Using a subquery is equivalent to performing two sequential queries and using the result of the first query as the search values in the second query.

- a. True
- b. False

**ORACLE** 

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

Answer: a

### **Summary**

In this lesson, you should have learned how to:

- Identify when a subquery can help solve a problem
- Write subqueries when a query is based on unknown values

```
SELECT select_list
FROM table
WHERE expr operator
(SELECT select_list
FROM table);
```

**ORACLE** 

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

In this lesson, you should have learned how to use subqueries. A subquery is a SELECT statement that is embedded in the clause of another SQL statement. Subqueries are useful when a query is based on a search criterion with unknown intermediate values.

Subqueries have the following characteristics:

- Can pass one row of data to a main statement that contains a single-row operator, such as =, <>, >, >=, <, or <=
- Can pass multiple rows of data to a main statement that contains a multiple-row operator, such as IN
- Are processed first by the Oracle server, after which the WHERE or HAVING clause uses the results
- Can contain group functions

### **Practice 8: Overview**

This practice covers the following topics:

- Creating subqueries to query values based on unknown criteria
- Using subqueries to find out the values that exist in one set of data and not in another

Oracle University and Egabi Solutions use only

Copyright © 2013, Oracle and/or its affiliates. All rights reserved.

In this practice, you write complex queries using nested SELECT statements.

For practice questions, you may want to create the inner query first. Make sure that it runs and produces the data that you anticipate before you code the outer query.
